# Senior QA Engineer (Mobile) — Take-home Exercise

Write automated tests for the sign-up, login and forms screens of a demo mobile app, and send us a GitHub link.

## The app

Test the **WebdriverIO Native Demo App v2.2.0**, an open-source React Native app made for practising mobile automation.

- **Android (required):** go to the GitHub release page at https://github.com/webdriverio/native-demo-app/releases/tag/v2.2.0, download `android.wdio.native.app.v2.2.0.apk` from the **Assets** list (direct download link), and install it on an emulator or a real device.
- **iOS (optional):** the same release includes a simulator build, `ios.simulator.wdio.native.app.v2.2.0.zip`.
- Use the prebuilt app; there is no need to build it from source.
- The app has no backend, so you don't need real accounts.

Use any mobile automation tool and language you like, for example Appium (Java, TypeScript or Python) or Maestro. Tell us in your README why you chose it.

## Core tests (required)

Automate at least these scenarios on Android. Each test should assert what the user sees, such as the dialog text or the error message.

| Area | Where in the app | Scenarios |
|---|---|---|
| Sign up | Login tab → Sign up | Successful sign-up shows the success dialog; an invalid email is rejected; mismatched passwords are rejected |
| Login | Login tab → Login | Successful login shows the success dialog; an invalid email is rejected; a password shorter than 8 characters is rejected |
| Forms | Forms tab | Typed text is echoed back; the switch toggles and its label updates; the "Active" button opens a native alert |

## Going further (optional)

Feel free to add more tests if you think they provide value, and tell us in your README why you chose them. A few reliable, readable tests are worth more than many flaky ones.

## What to submit

Email a link to your GitHub repository. The repository can be public.

Your README should cover:

- How to set up and run the tests
- Which tool you chose and why
- How the project is organised
- What you would do next with more time
- Whether you used AI tools, and how (that's fine, just tell us)

Please keep your commit history rather than squashing it into one commit.

## How we review

We will clone your repository and run the tests by following your README. We look at:

- **Reliability:** the tests pass consistently, use stable locators, wait for conditions rather than fixed sleeps, and don't depend on each other.
- **Readability:** the code is easy to follow and to extend with new tests.
- **Test design:** sensible scenarios with clear expected results.
- **Communication:** a clear, honest README and well-written bug reports.

If we move forward, we'll schedule a 60-minute call where you walk us through your solution and make a small change live.
